Review – How machine learns from data?

- Define a function to be learned: $y = f(x)$
- Define a loss function $\mathcal{L}$ to describe the error between $\hat{y} = f(x)$ and y
- Find the optimal parameters of f that minimize $\mathcal{L}$

Review – Gradient descent to find optimal parameters that minimize the loss

Gradient descent to find optimal parameters that minimize the loss

Suppose that θ has two variables $\{\theta_1, \theta_2\}$

Randomly start at $\theta^0 = \begin{bmatrix} \theta_1^0 \\ \theta_2^0 \end{bmatrix}$

$$\nabla L(\theta) = \begin{bmatrix} \partial L(\theta_1)/\partial \theta_1 \\ \partial L(\theta_2)/\partial \theta_2 \end{bmatrix}$$

$$\begin{bmatrix} \theta_1^1 \\ \theta_2^1 \end{bmatrix} = \begin{bmatrix} \theta_1^0 \\ \theta_2^0 \end{bmatrix} - \eta \begin{bmatrix} \partial L(\theta_1^0)/\partial \theta_1 \\ \partial L(\theta_2^0)/\partial \theta_2 \end{bmatrix} \Rightarrow \theta^1 = \theta^0 - \eta \nabla L(\theta^0)$$

$$\begin{bmatrix} \theta_1^2 \\ \theta_2^2 \end{bmatrix} = \begin{bmatrix} \theta_1^1 \\ \theta_2^1 \end{bmatrix} - \eta \begin{bmatrix} \partial L(\theta_1^1)/\partial \theta_1 \\ \partial L(\theta_2^1)/\partial \theta_2 \end{bmatrix} \Rightarrow \theta^2 = \theta^1 - \eta \nabla L(\theta^1)$$

More details about gradient descent

```
# initialize NN weights
for name, param in MyNet.named_parameters():
  if(param.requires_grad):
    torch.nn.init.normal_(param, mean=0.0, std=0.02)
loss_func = torch.nn.MSELoss()
optimizer = torch.optim.Adam(MyNet.parameters(), lr=0.0003)

# train NN
print("epoch", end=": ")
epoch_lossLst=[]
for epoch in range(1, 700):
  if(epoch%100 == 0):
    print(epoch, end=",")
  for (batchX, batchY) in loader:
    batchY_hat = MyNet(batchX)
    loss = loss_func(batchY_hat, batchY)
    epoch_lossLst.append(float(loss))
    optimizer.zero_grad()
    loss.backward()
    optimizer.step()
```

Give different parameters different lr?

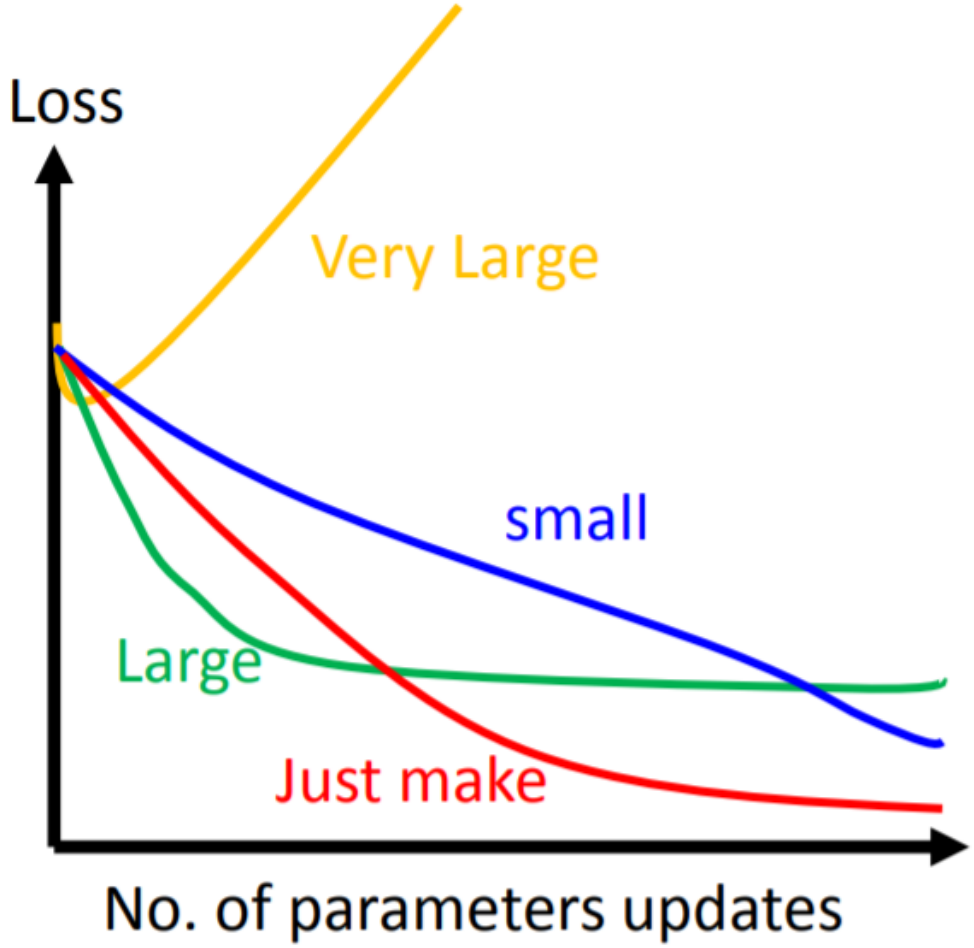
Fixed or adaptive lr ?

Why mini-batch?

Learning rates

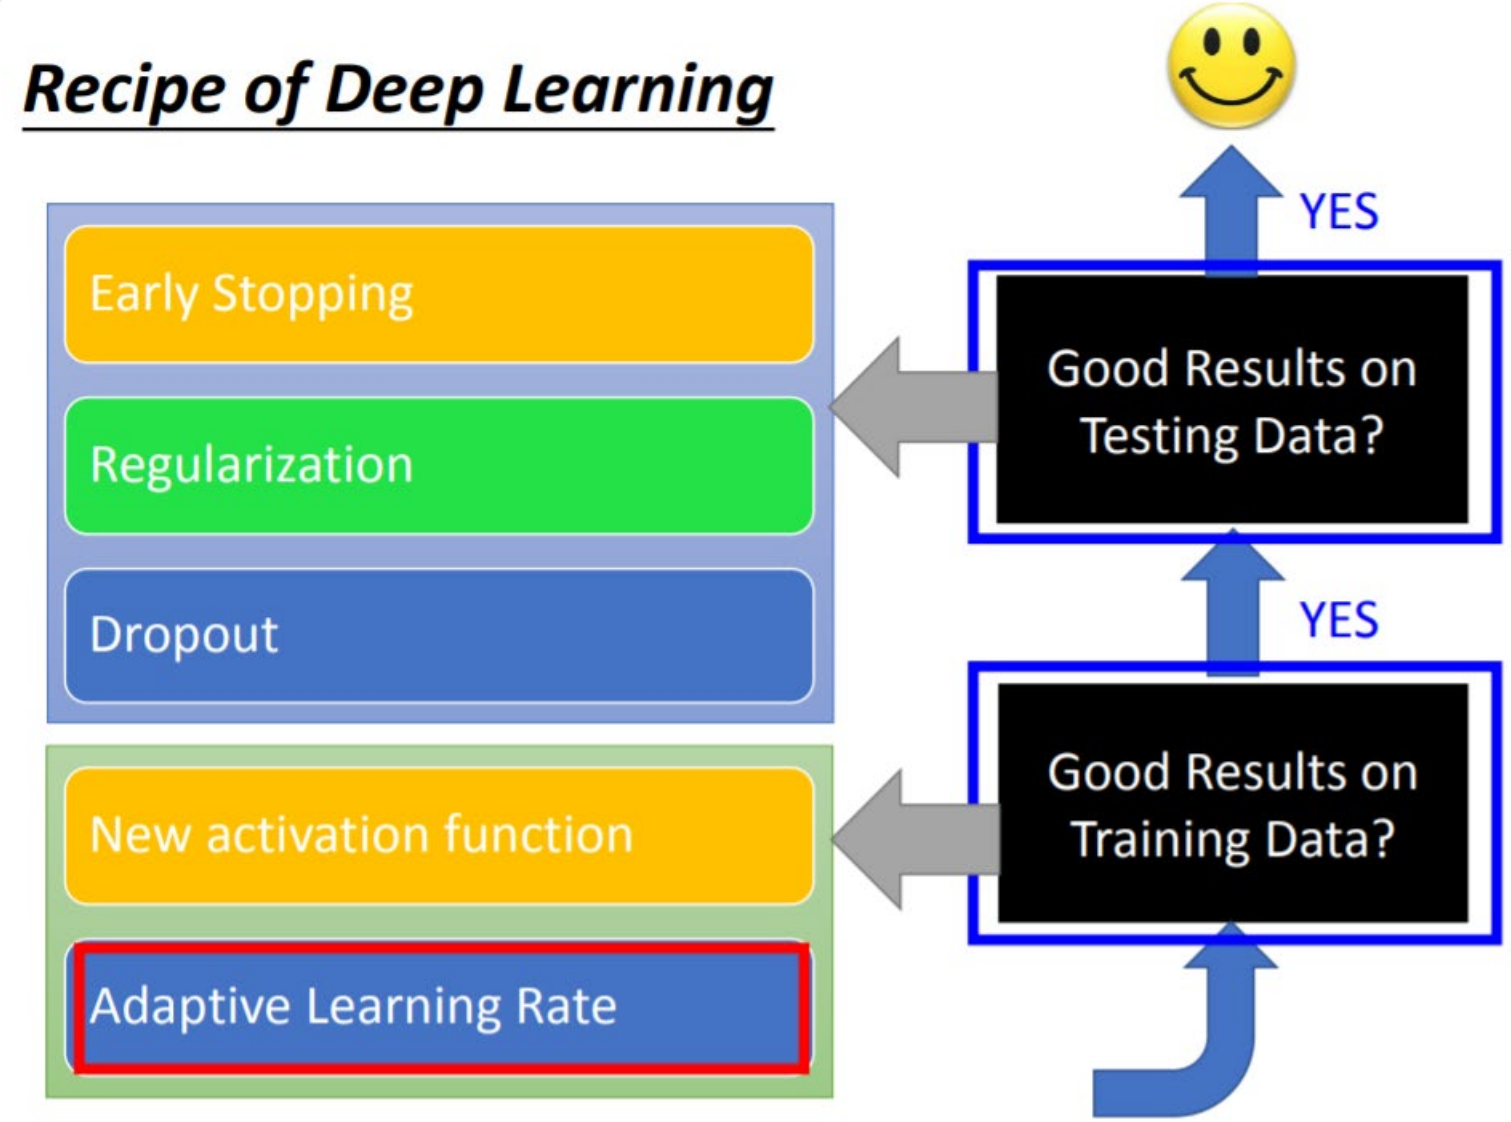
3. Gradient descent.ipynb

- 0.5
- 0.05
- 0.0003



Reference: 李弘毅 ML Lecture 3-1
https://youtu.be/yKKNr-QKz2Q

Adaptive learning rates



Reference: 李弘毅 ML Lecture 9-1 https://youtu.be/xki61j7z-30

Learning rate schedule

- Reduce the learning rate by some factor every few epochs.

  At the beginning, we are far from the destination, so we use larger learning rate

  After several epochs, we are close to the destination, so we reduce the learning rate

3. Gradient descent.ipynb

Adagrad

- Give different parameters different learning rates.
- Divide the learning rate of each parameter by the root mean square of its previous derivatives

η^t : adaptive lr

$$w^{t+1} \leftarrow w^t - \frac{\eta^t}{\sigma^t} g^t \qquad g^t = \frac{\partial L(\theta^t)}{\partial w}$$

$$w^1 \leftarrow w^0 - \frac{\eta^0}{\sigma^0} g^0 \qquad \sigma^0 = \sqrt{(g^0)^2}$$

$$w^2 \leftarrow w^1 - \frac{\eta^1}{\sigma^1} g^1 \qquad \sigma^1 = \sqrt{\frac{1}{2}[(g^0)^2 + (g^1)^2]}$$

$$w^3 \leftarrow w^2 - \frac{\eta^2}{\sigma^2} g^2 \qquad \sigma^2 = \sqrt{\frac{1}{3}[(g^0)^2 + (g^1)^2 + (g^2)^2]}$$

$$\vdots$$

$$w^{t+1} \leftarrow w^t - \frac{\eta^t}{\sigma^t} g^t \qquad \sigma^t = \sqrt{\frac{1}{t+1}\sum_{i=0}^{t} (g^i)^2}$$

Reference: 李弘毅 ML Lecture 3-1 https://youtu.be/yKKNr-QKz2Q

Why divided by root mean square of previous derivatives?

$$w^{t+1} \leftarrow w^t - \frac{\eta^t}{\sigma^t} g^t$$

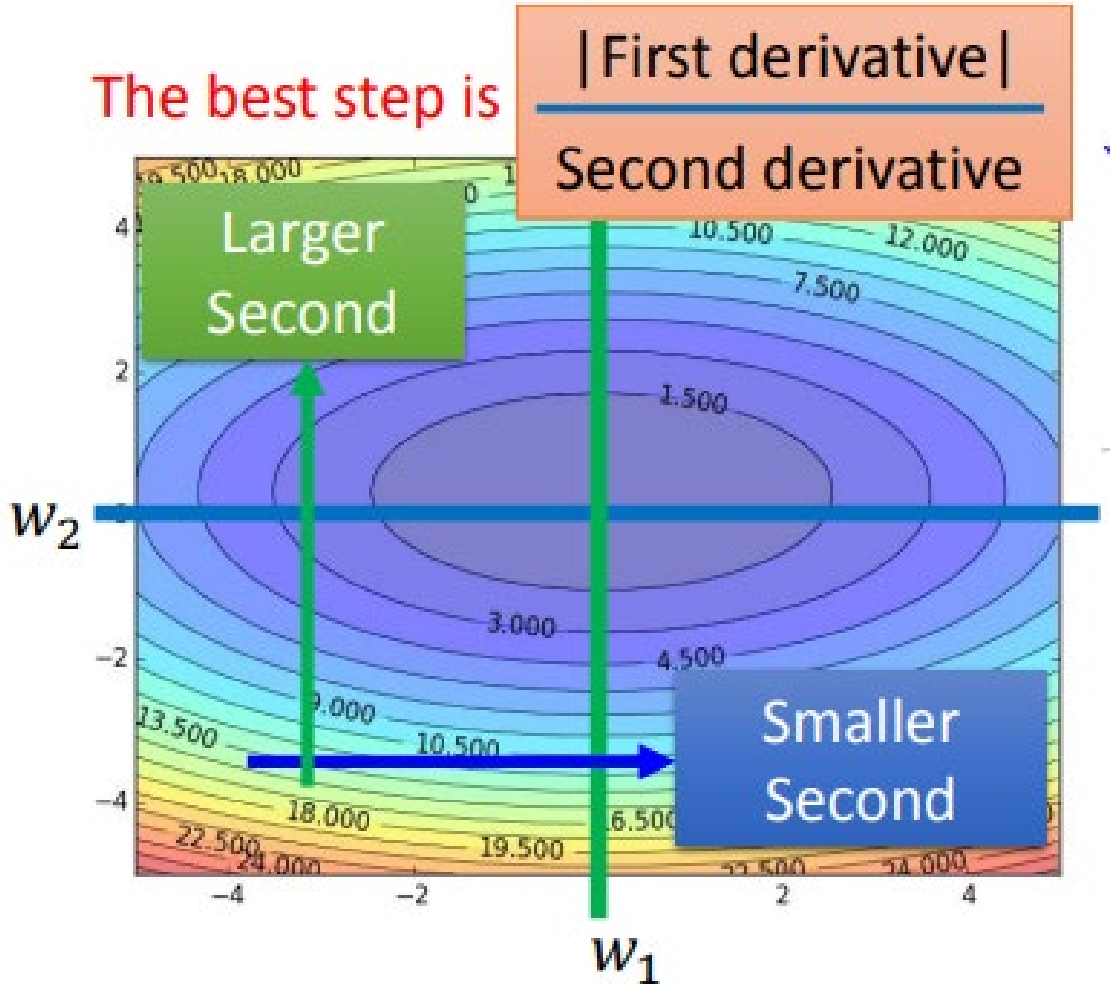
$$\eta^t = \frac{\eta}{\sqrt{t+1}}$$

$$\sigma^t = \sqrt{\frac{1}{t+1}\sum_{t=0}^{t}(g^t)^2}$$

$$w^{t+1} \leftarrow w^t - \frac{\eta}{\sqrt{\sum_{i=0}^{t}(g^i)^2}} g^t$$

Use first derivative to estimate second derivative

The best step is $\frac{|\text{First derivative}|}{\text{Second derivative}}$



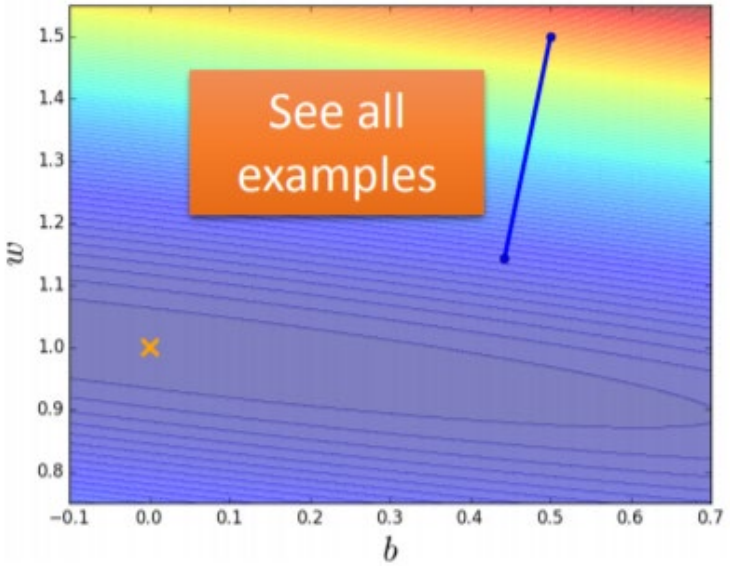
Stochastic Gradient Descent (SGD)

- Make the training faster
- Loss for only one sample

Gradient Descent

Update after seeing all examples

$$\theta^t = \theta^{t-1} - \eta \nabla L(\theta^{t-1})$$



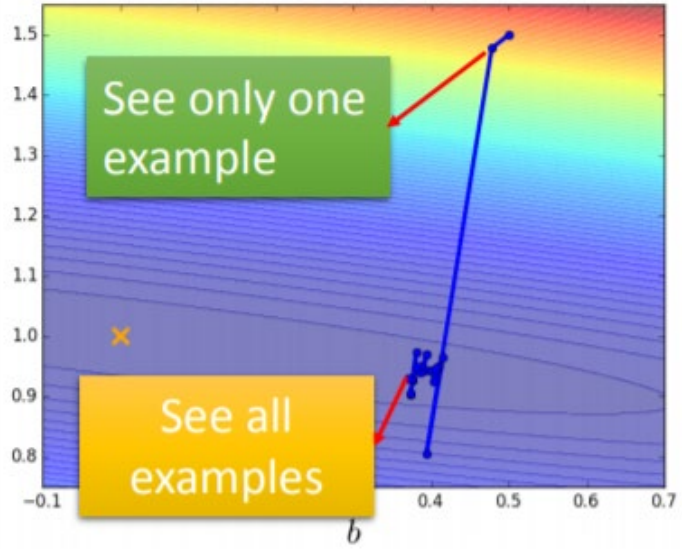
$$\nabla L(\theta) = \begin{bmatrix} \partial L / \partial w_1 \\ \vdots \\ \partial L / \partial w_K \end{bmatrix}$$

Stochastic Gradient Descent

Update for each example

If there are 20 examples, 20 times faster.

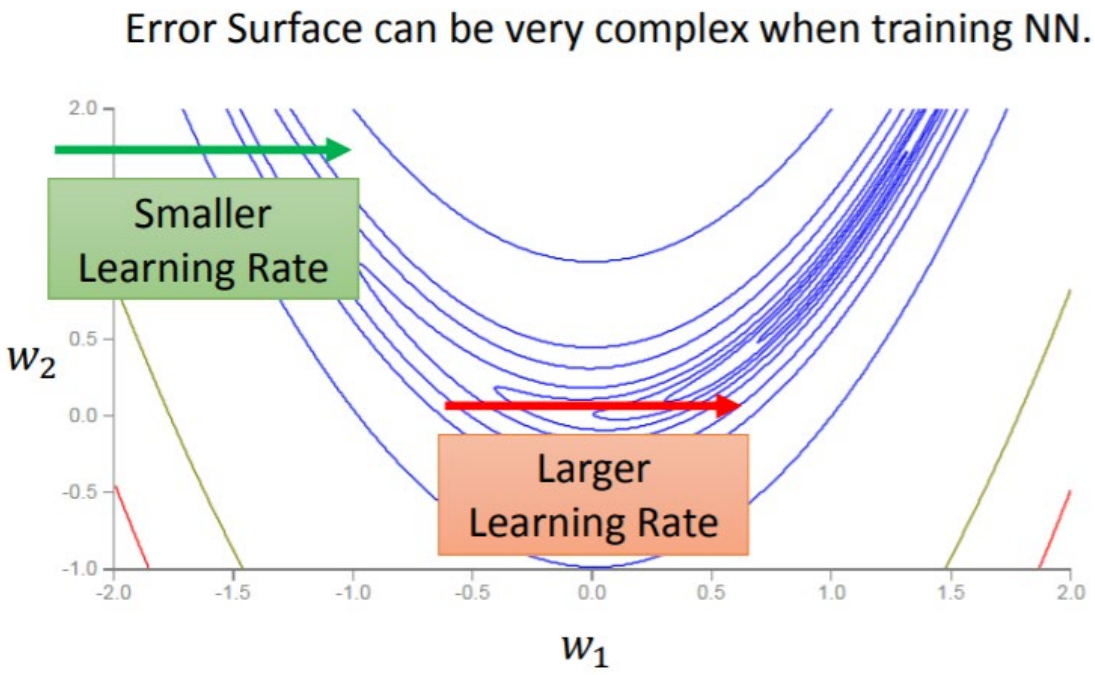
$$\theta^t = \theta^{t-1} - \eta \nabla L^n (\theta^{t-1})$$



$$\nabla L(\theta) = \begin{bmatrix} \partial L^n / \partial w_1 \\ \vdots \\ \partial L^n / \partial w_K \end{bmatrix}$$

Reference: 李弘毅 ML Lecture 3-1 https://youtu.be/yKKNr-QKz2Q

RMS Prop



$$w^1 \leftarrow w^0 - \frac{\eta}{\sigma^0} g^0 \qquad \sigma^0 = g^0$$

$$w^2 \leftarrow w^1 - \frac{\eta}{\sigma^1} g^1 \qquad \sigma^1 = \sqrt{\alpha(\sigma^0)^2 + (1-\alpha)(g^1)^2}$$

$$w^3 \leftarrow w^2 - \frac{\eta}{\sigma^2} g^2 \qquad \sigma^2 = \sqrt{\alpha(\sigma^1)^2 + (1-\alpha)(g^2)^2}$$

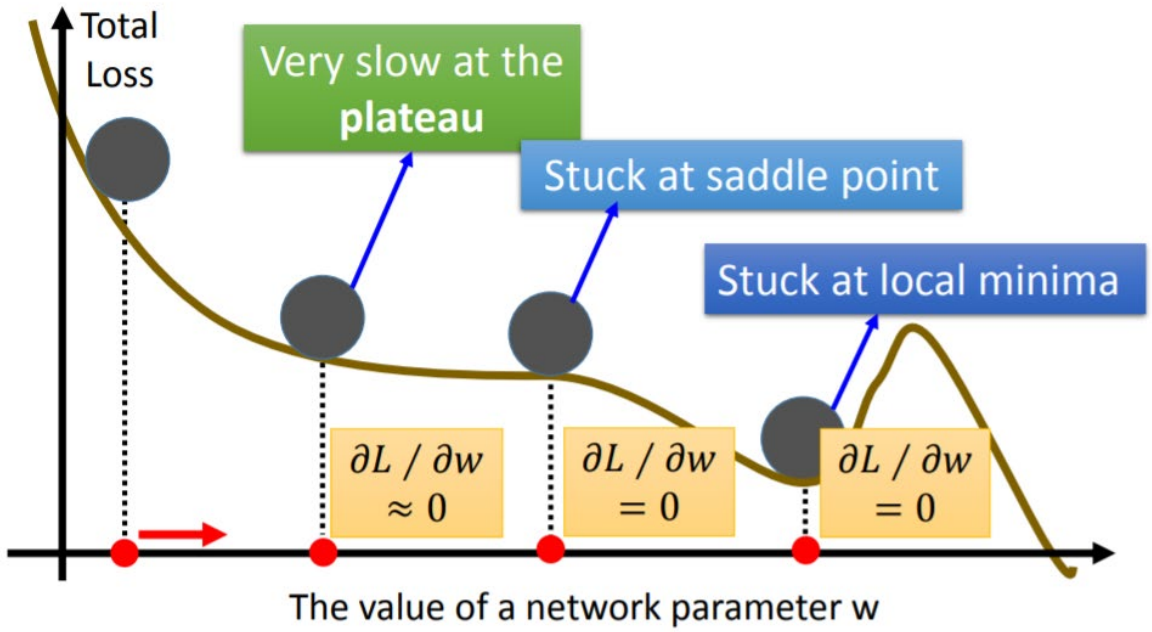
$$\vdots$$

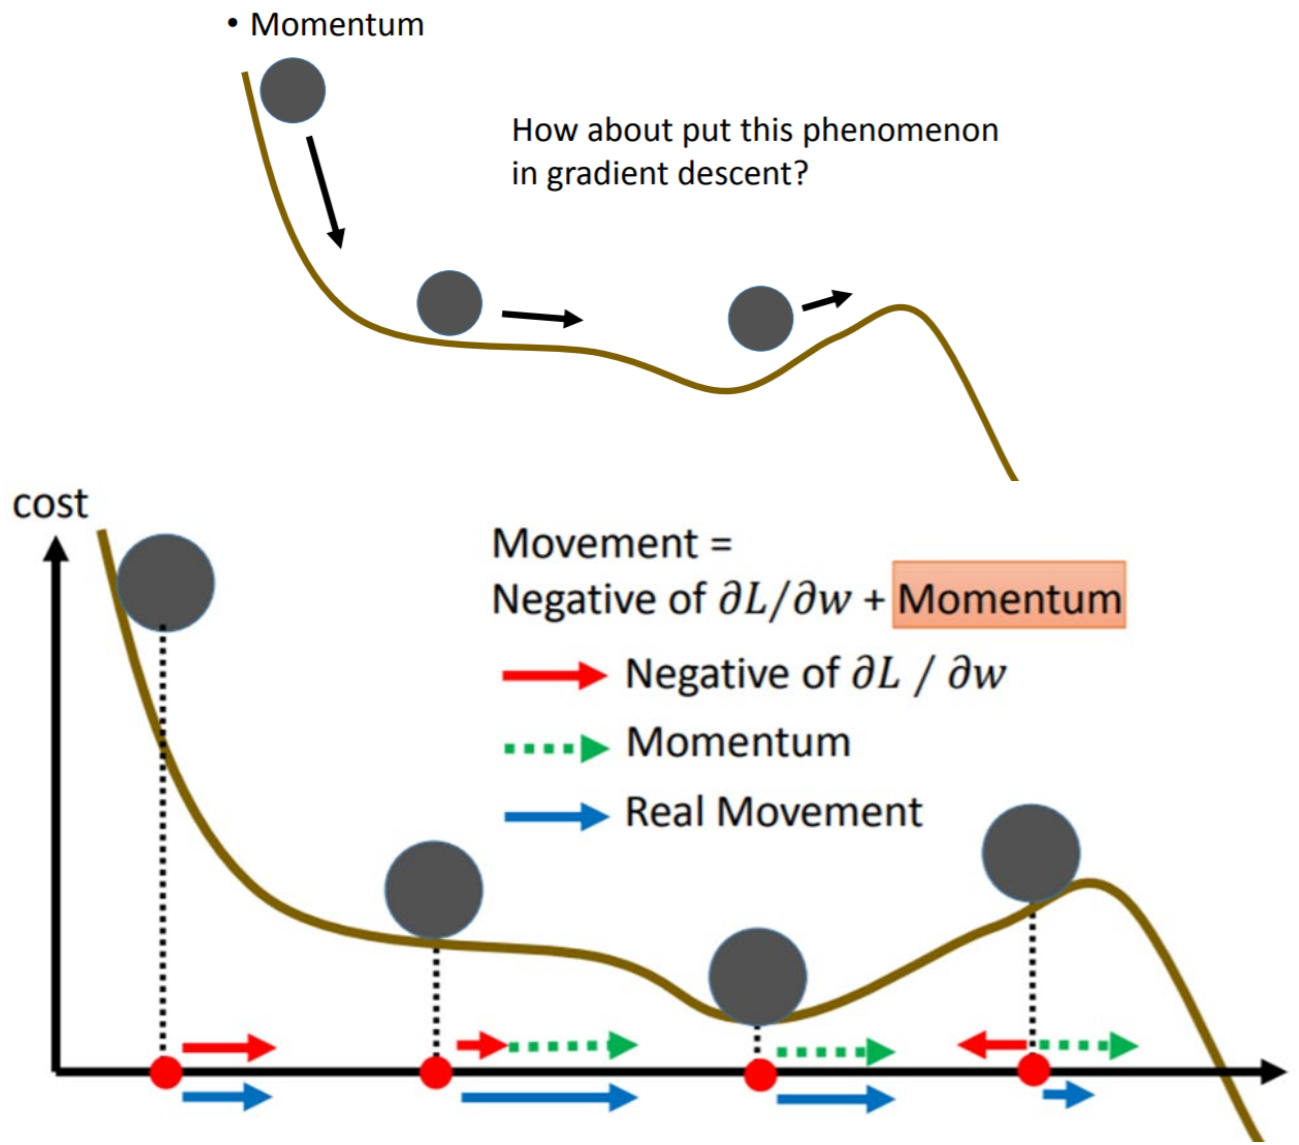
$$w^{t+1} \leftarrow w^t - \frac{\eta}{\sigma^t} g^t \qquad \sigma^t = \sqrt{\alpha(\sigma^{t-1})^2 + (1-\alpha)(g^t)^2}$$

Root Mean Square of the gradients with previous gradients being decayed

Reference: 李弘毅 ML Lecture 9-1 https://youtu.be/xki61j7z-30

Consider gradient + momentum

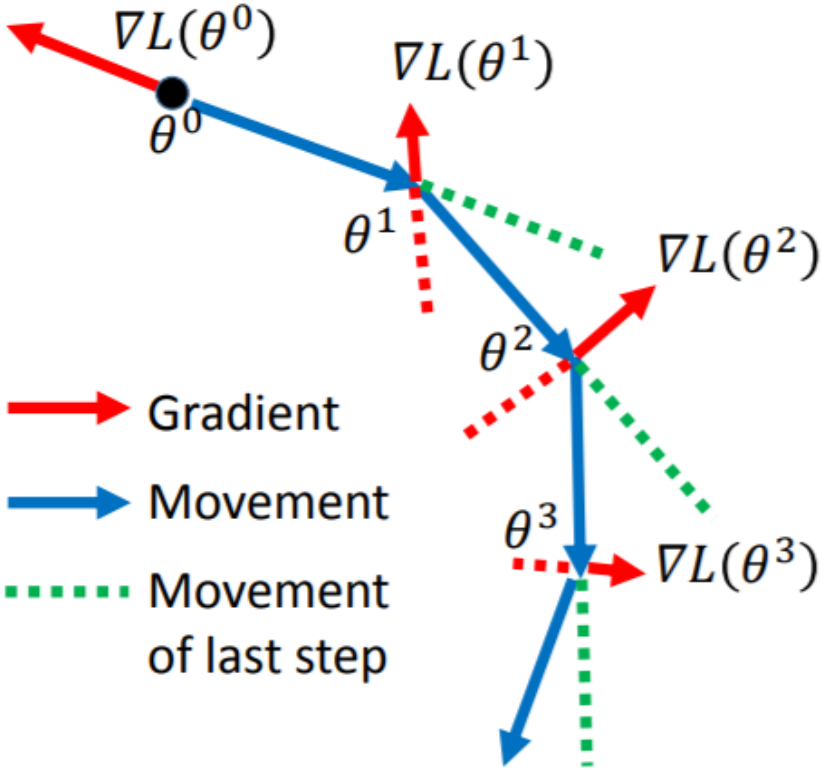




Reference: 李弘毅 ML Lecture 9-1 https://youtu.be/xki61j7z-30

Consider gradient + momentum

Movement: movement of last step minus gradient at present



Start at point θ^0

Movement $v^0=0$

Compute gradient at θ^0

Movement $v^1 = \lambda v^0 - \eta\nabla L(\theta^0)$

Move to $\theta^1 = \theta^0 + v^1$

Compute gradient at θ^1

Movement $v^2 = \lambda v^1 - \eta\nabla L(\theta^1)$

Move to $\theta^2 = \theta^1 + v^2$

Movement not just based on gradient, but previous movement.

v^i is actually the weighted sum of all the previous gradient: $\nabla L(\theta^0), \nabla L(\theta^1), \ldots \nabla L(\theta^{i-1})$

$v^0 = 0$

$v^1 = -\eta\nabla L(\theta^0)$

$v^2 = -\lambda\eta\nabla L(\theta^0) - \eta\nabla L(\theta^1)$

⋮

Adam

RMSProp + Momentum

Algorithm 1: *Adam*, our proposed algorithm for stochastic optimization. See section 2 for details, and for a slightly more efficient (but less clear) order of computation. g_t^2 indicates the elementwise square $g_t \odot g_t$. Good default settings for the tested machine learning problems are $\alpha = 0.001$, $\beta_1 = 0.9$, $\beta_2 = 0.999$ and $\epsilon = 10^{-8}$. All operations on vectors are element-wise. With β_1^t and β_2^t we denote β_1 and β_2 to the power t.

Require: α: Stepsize
Require: $\beta_1, \beta_2 \in [0, 1)$: Exponential decay rates for the moment estimates
Require: $f(\theta)$: Stochastic objective function with parameters θ
Require: θ_0: Initial parameter vector
$m_0 \leftarrow 0$ (Initialize 1st moment vector) → for momentum
$v_0 \leftarrow 0$ (Initialize 2nd moment vector) → for RMSprop
$t \leftarrow 0$ (Initialize timestep)
while θ_t not converged **do**
$t \leftarrow t + 1$
$g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$ (Get gradients w.r.t. stochastic objective at timestep t)
$m_t \leftarrow \beta_1 \cdot m_{t-1} + (1 - \beta_1) \cdot g_t$ (Update biased first moment estimate)
$v_t \leftarrow \beta_2 \cdot v_{t-1} + (1 - \beta_2) \cdot g_t^2$ (Update biased second raw moment estimate)
$\widehat{m}_t \leftarrow m_t / (1 - \beta_1^t)$ (Compute bias-corrected first moment estimate)
$\widehat{v}_t \leftarrow v_t / (1 - \beta_2^t)$ (Compute bias-corrected second raw moment estimate)
$\theta_t \leftarrow \theta_{t-1} - \alpha \cdot \widehat{m}_t / (\sqrt{\widehat{v}_t} + \epsilon)$ (Update parameters)
end while
return θ_t (Resulting parameters)

Reference: 李弘毅 ML Lecture 9-1 https://youtu.be/xki61j7z-30

Why gradient decent can find local minimum?

Based on Taylor Series:

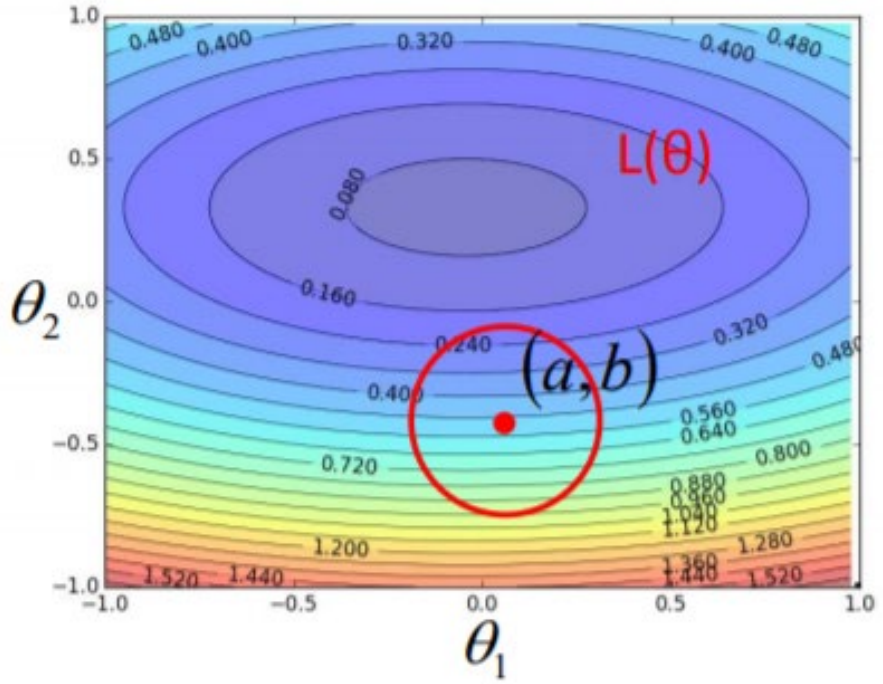
If the red circle is ***small enough***, in the red circle

$$L(\theta) \approx L(a,b) + \frac{\partial L(a,b)}{\partial \theta_1}(\theta_1 - a) + \frac{\partial L(a,b)}{\partial \theta_2}(\theta_2 - b)$$

$$s = L(a,b)$$

$$u = \frac{\partial L(a,b)}{\partial \theta_1}, v = \frac{\partial L(a,b)}{\partial \theta_2}$$

$$L(\theta) \approx s + u(\theta_1 - a) + v(\theta_2 - b)$$



Reference: 李弘毅 ML Lecture 3-1 https://youtu.be/yKKNr-QKz2Q

Why gradient decent can find local minimum?

Red Circle: (If the radius is small)

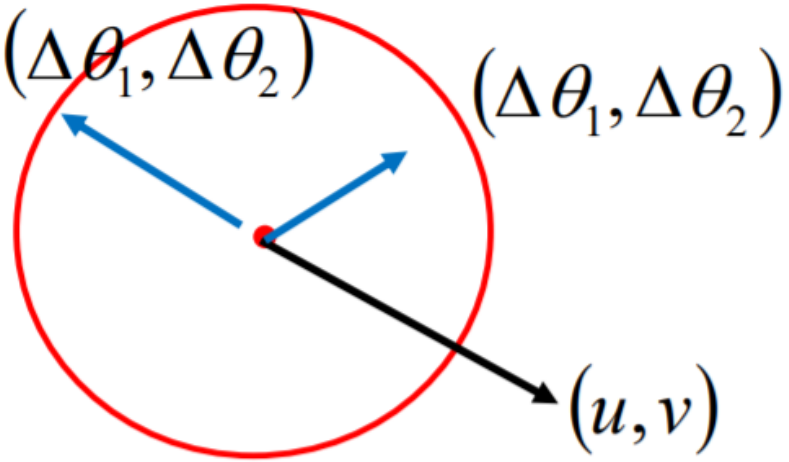
$$L(\theta) \approx s + u(\theta_1 - a) + v(\theta_2 - b)$$

$$\Delta\theta_1 \qquad \Delta\theta_2$$

Find θ_1 and θ_2 in the red circle ***minimizing*** L(θ)

$$(\theta_1 - a)^2 + (\theta_2 - b)^2 \le d^2$$

$$\Delta\theta_1 \qquad \Delta\theta_2$$



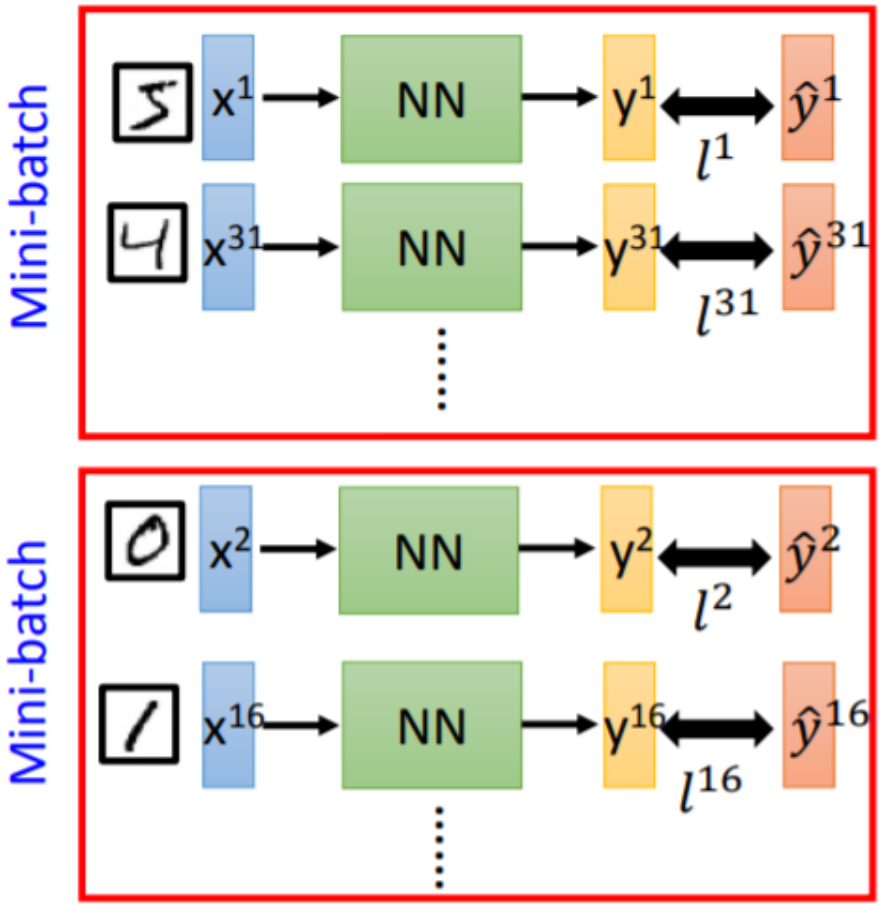
To minimize L(θ)

$$\begin{bmatrix} \Delta\theta_1 \\ \Delta\theta_2 \end{bmatrix} = -\eta \begin{bmatrix} u \\ v \end{bmatrix} \Rightarrow \begin{bmatrix} \theta_1 \\ \theta_2 \end{bmatrix} = \begin{bmatrix} a \\ b \end{bmatrix} - \eta \begin{bmatrix} u \\ v \end{bmatrix}$$

Reference: 李弘毅 ML Lecture 3-1 https://youtu.be/yKKNr-QKz2Q

We do not really minimize total loss!

Mini-batch



- Randomly initialize network parameters
- Pick the 1st batch

  $L' = l^1 + l^{31} + \cdots$

  Update parameters once
- Pick the 2nd batch

  $L'' = l^2 + l^{16} + \cdots$

  Update parameters once

  ⋮
- Until all mini-batches have been picked

one epoch

Repeat the above process

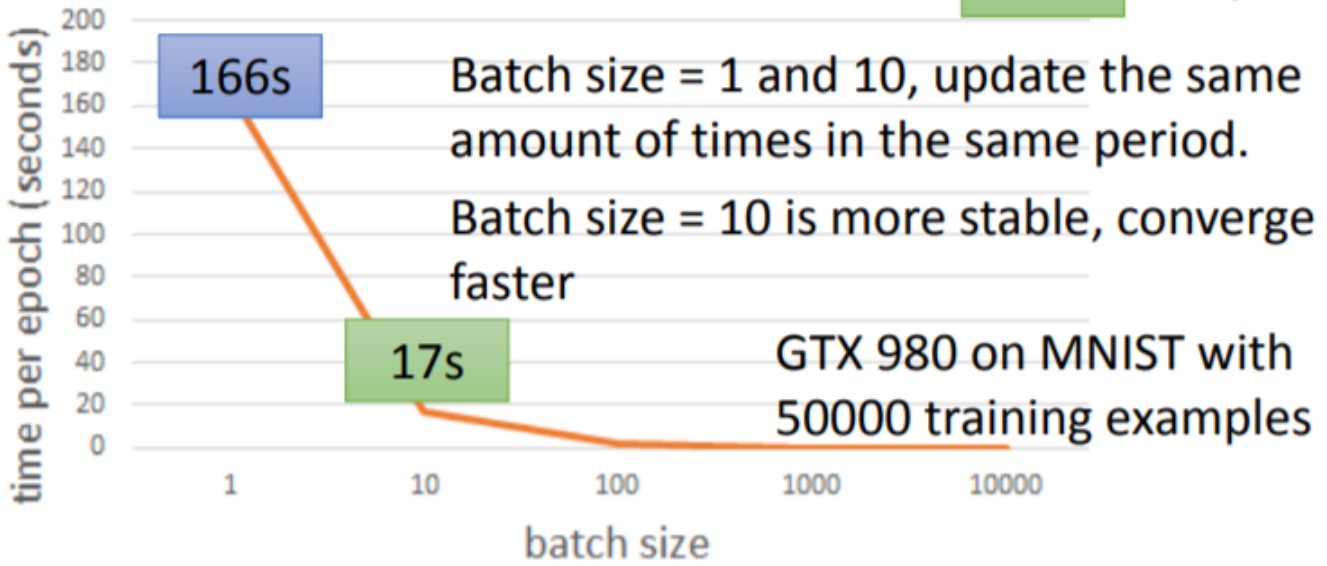
Reference: 李弘毅 ML Lecture 8-1 https://youtu.be/Lx3l4lOrquw

Batch size influences both speed and performance. You have to tune it.

Speed

Very large batch size can yield worse performance

- Smaller batch size means more updates in one epoch
  - E.g. 50000 examples
  - batch size = 1, 50000 updates in one epoch — 166s — 1 epoch
  - batch size = 10. 5000 updates in one epoch — 17s — 10 epoch



Reference: 李弘毅 ML Lecture 8-1 https://youtu.be/Lx3l4lOrquw
